

Turning Account Research into a Trackable AI Workflow

AI Account Intelligence & Outreach Ops System

One-line version: this system turns an added target company, AI-prepared research, and status writeback into a traceable business workflow. AI prepares the first pass; humans keep the final say.

The project starts from a very ordinary business problem

Before a B2B team reaches out to a potential customer, someone needs to answer a simple question: is this company worth our time? In practice, that means checking public company information, judging fit against a target customer profile, preparing a contextual outreach draft, and recording the result.

The information is scattered like sticky notes on a wall. This project turns those notes into a workflow. It is not an auto-send email bot; it is a research assistant that prepares the folder but does not hit send.

How the system works

The current system takes a new Zapier Table row, creates a run, triggers the worker, processes the company, and writes run_id and status back to the same row.

Why these technologies were chosen

Choice	Reason
Zapier Tables	Gives non-technical users a spreadsheet-like way to submit companies.
FastAPI	Provides a clear and lightweight service entry point.
Worker	Separates request intake from longer background processing.
PostgreSQL / Neon	Acts as the system of record for runs, companies, drafts, and events.
X-API-Key	Adds a simple door key to protect public workflow endpoints.

Key design choices

No automatic sending

In a real business workflow, AI should not represent the team externally without review. The system prepares drafts;

Zapier is not the AI brain

Zapier starts the workflow, while the core logic lives in the API, database, and worker. This makes the system easier to

humans approve.

trace and debug.

Every run has a run_id

The run_id is like a tracking number. It lets the system trace exactly what happened to one request.

Results return to the table

Users do not need to read server logs. The table shows statuses such as sent_to_review or failed.

Methods and benefits

The system follows a simple pattern: register the request, process it in the background, validate the result, and write status back. That makes the AI workflow less like a black box and more like a business operation with a front desk, back office, quality check, and status board.

```
POST /runs      -> create run, return run_id and queued
Worker         -> find and process queued work
Validation     -> check evidence and confidence
Zapier writeback -> update original table row with run_id/status
```

The benefit is clarity: business users can understand it, technical users can debug it, and future Slack, HubSpot, and reporting layers have clear places to connect.

What exists today

Capability	Current result
Zapier entry	A new company row automatically triggers the workflow.
Cloud API	The Render-hosted FastAPI service can create and retrieve runs.
Database record	Neon/PostgreSQL stores runs, companies, drafts, and events.
Table writeback	Zapier Table receives run_id and status.
Verification	Current test result: 22 tests OK.

What comes next

Next capability	Meaning
Live web research	Use Tavily to read company websites, news, and public sources.
Real CrewAI multi-agent flow	Split the work across Researcher, Analyst, and Writer roles.
Slack human review	Send drafts to Slack with Approve, Reject, and Request changes buttons.
HubSpot sync	Only approved outputs enter the CRM.
Quality evaluation report	Test 15 real companies for grounding rate, failure rate, latency, and review rate.
More production-ready worker	Add queueing, retry, concurrency control, and duplicate protection.

The final target is not a demo that merely runs. It is an AI agent workflow that shows real business-system thinking: traceable, reviewable, explainable, and clear about when a human should take over.
